

Interning

Introduction

Interning is re-using objects of equal value on-demand instead of creating new objects. This is done for memory efficiency. Frequently used for numbers and strings in different programming languages.

```
a = 120
b = 120

print(a is b) # True

c = 2000
d = 2000

print(c is d) # False
```

In the above code, `120` is intered by the Python interpreter but not `2000` . Python's integer interning is done only for numbers in the range: `[-5, 256]`

Python interpreter also interns small strings.

```
a = "abcd"
b = "abcd"

print(a is b) # True

# Both text are the same
c = "Lorem ipsum dolor sit amet consectetur adipisicing elit. Consequuntur perferendis iste ipsa nat
d = "Lorem ipsum dolor sit amet consectetur adipisicing elit. Consequuntur perferendis iste ipsa nat

print(c is d) # False
```

Strings in python can be manually interned using `sys.intern` function.

```
a,b=8,8
c=8
```

Likewise, in the above code, only 1 integer object is created.

Practice Resources

Programs

The programs are listed in no specific order.

1. **is prime number**: A program that takes in a number n and outputs whether its a [prime number](#) or not.
2. **factors**: Take in a number from user. Output all of its factors.
3. **n-th factorial**: A program that takes in a number n and outputs n-th [factorial](#).
4. **is perfect number**: A program that takes in a number n and outputs whether its a [perfect number](#).
5. **fibonacci numbers**: A program that takes in a number n and prints all [fibonacci numbers](#) less than or equal to n .
6. **determinant of matrix**: Take in a matrix from user. Output the determinant of the matrix. First try for 2×2 . Then go higher-ordered matrices.
7. **pascal's triangle**: Take n from user input. Print [pascal's triangle](#) to n rows.
8. **is valid palindrome**: Take a string input from user. Output if the input is palindrome or not. A phrase is a palindrome if, after converting all uppercase letters into lowercase letters and removing all non-alphanumeric characters, it reads the same forward and backward. Alphanumeric characters include letters and numbers. Try not to use `[::-1]`.
9. **armstrong numbers**: Take n from user input. Print all [armstrong numbers](#) (in base 10, of course) between 0 and n (inclusive).
10. **letter analysis**: Take a text input from user. Find how many times each letter is being used in that string. Use a `dictionary` to store the data. Output the final results. Try to read the text from a `.txt` file as well.
11. **word length analysis**: Take a string input from user. Print length of each word separated by a space. Try to include the summary using a `dictionary`.
12. **letter expanding**: A program that converts `b3j8k2` to `bbbjjjjjjkk`. The number can be 1 to 99.
13. **binary addition**: Take in 2 numbers in binary (as strings) and output the sum of both numbers. Try not to use `bin` function.

14. **big integer addition**: Given a *very large integer* represented as a list, where each `digits[i]` is the i^{th} digit of the integer. The digits are ordered from most significant to least significant in left-to-right order. Increment the large integer by one and return the resulting array of digits. Don't construct a `int` object.

Platforms

- Codewars - <https://codewars.com> (my most preferred one)
- HackerRank - <https://hackerrank.com>
- Leetcode - <https://leetcode.com> (my least preferred one)

⚠ Hard Problems

If a problem from one of these platforms feels too hard for you, you can just skip and do another problem.

One's & Two's Complement

One's complement

The ones' complement of a binary number is the value obtained by flipping all the bits in the binary representation of the number.

- If one's complement of a is b , then one's complement of b is a .
- Binary representation of $a + b$ will include all 1 s.

One's complement system

In which negative numbers are represented by the inverse of the binary representations of their corresponding positive numbers. First bit denotes the sign of the number.

- Positive numbers are denoted as basic binary numbers with 0 as the MSB.
- Negative values are denoted by the one's complement of their absolute value.

For example, to find the one's complement system representation of -7 , one's complement of 7 must be found. $7 = 0111_2$. One's complement of -7 is 1000 .

Two's complement

In which negative numbers are represented using the MSB (sign bit).

If MSB is:

- **1** : negative
- **0** : positive

Positive numbers are represented as basic binary numbers with an additional **0** as the sign bit.

For example:

Following equation can be used to convert a number in two's complement form to decimal.

$$b = -2^{n-1}b_{n-1} + \sum_{k=0}^{n-2} 2^k b_k$$

Steps

1. Starting with the absolute binary representation of the number
2. Add a leading **0** bit being a sign bit
3. Find the one's complement: flip all bits (which effectively subtracts the value from -1)
4. Add 1, ignoring any overflows
